Abstract- In this paper we intend to implement a real time Face detection and tracking the head poses position’s from high definition video using Haar Classifier through Raspberry Pi BCM2835 CPU processor which is an combination of SoC with GPU based Architecture. OVA5647 CMOS Image sensor with 5-megapixel used for obtaining high definition video H.264 video data via GPU’s hardware video decoder to improve playback of H.264 Video data supporting from 1080p at 30fps with complete user control over formatting and output data transfer also supporting with 720p/60HD video in full field of View(FOV). SimpleCV and OpenCV libraries are used for face detection and tracking the head poses position. The experimental result computed by using computer vision SimpleCV and OpenCV framework libraries along with above mentioned hardware results in a sustained throughput of 30 fps under 1080p resolutions for with higher accuracy and speediness for face detection and tracking the head poses position.

Index Terms- Computer Vision, Face Detection, Haar Classifier, Tracking

I. INTRODUCTION

Face detection from an image has been playing a vital role in the active research area, especially in computer vision research for more decades beginning from Eigen Faces, Principal Component Analysis, for numerous applications from monitoring, surveillance, Biometric and Human Computer Interaction. Face detection proposed by Viola and Jones’s, Face detection is most used face detection is based on statistical methods for rapid frontal face detection system using Haar-like features. Analyzing the pixels for face detection is time consuming and difficult to accomplish because of the wide variations of shape and pigmentation within a human face.

Viola and Jones devised an algorithm, called Haar Classifiers, to rapidly detect any object, including human faces, using AdaBoost classifier cascades that are based on Haar-like features and not pixels. Haar –Like features widely used for identifying and locating human face in images regardless of size, position and condition including color, texture and motion under dynamic environments and the resources of the systems are considered to be monopolized by face detection.

In this paper we intend to implement the Haar-Classifier for Face detection and tracking based on the Haar-Features on System on Chip (SoC) for use in a human machine interface and action interpretation. Haar-like features can be computed at any scale or location in constant time using the integral image representation for images. The problem in analysis the pose is binary classification, which needs to be classified in every images and segregate data belonging to the class of interest (i.e. faces), or not. Most of the researchers are contributing focused to the two major main aspects of the problem: Haar-like feature and Classifier. Haar-Like features are used for selecting classes of features by improving the performance of the classifier based on the trained set of data pertaining to them. Haar Classifier adapts the existing classification algorithms to the detection and recognition problems.

II. RELATED WORKS

Robust and real-time face detection place a vital role in many of the application scenarios like access control, surveillance scenarios, gaming, human-computer interaction, etc. Viola and Jones devised an algorithm, called Haar Classifiers, to rapidly detect any object, including human faces, using Haar classifier cascades that are based on Haar –Like features. Haar-like features and not pixels. Different types of methods are available for detecting the face and recognition: Principal Component Analysis (PCA), Linear Discriminate Analysis (LDA), Support Vector Machines (SVM) Independent Component Analysis (ICA), Local Binary Pattern (LBP), and more recently Sparse Representation (SR) based methods. A recent survey on face recognition algorithms can be found in. Different algorithm are existing for performing and analysis of face detection with each of its own weakness and strengths related to use of flesh tones, some use contours, and other are even more complex involving templates, neural networks, or filters few of these algorithm are computationally expensive. There has been little work in the literature during the last years about real-time face detection at HDTV resolutions. Face detection
Real Time Face Detection and Tracking Using Haar Classifier on SoC

13

algorithm using Haar-like features was described by Viola and Jones [14] and now it and a range of its modifications are widely spread in many applications. One of these modifications [15] was implemented in OpenCV library [16]. The OpenCV implementation compiled with OpenMP option provides only 4.5 frames per second on 4-core CPU. It’s too slow to process HD stream in real time. As a solution to this problem a parallel modification of OpenCV algorithm for GPU has been developed.

Some parallel versions of face detection algorithm using Haar-like features [17, 18, 19]. The algorithm introduced by Hefenbrock [16] was the first realization of a face detection algorithm using GPU we could find.

It showed an effect of using GPU versus CPU. But the algorithm could not process a stream with resolution 640x480 in real time. The next parallel implementation is found in Obukhov’s algorithm [20]. It’s a single realization that uses GPU and can work with OpenCV classifiers without modification that is why modern versions of OpenCV library include it (test result of the algorithm is presented in corresponding section of the paper). The main problem of the algorithm is texture memory usage for classifier storing because texture memory is not as effective for general operation as cached global memory on modern GPU.

Section III presents to the face detection mechanism that uses Haar Classifiers based on Haar-like features. Section II refers to related works. Section IV presents the face detection design and analysis with Cascade Haar Classifier tracking mechanism based on a Haar-Like features approach. Section V presents the System overview obtained by implementing the Haar Classifier on System on Chip (Raspberry Pi). Further section real time data results are presented where it can be seen that faces are detected in images from High Definition video streaming from Image Sensor. Section VI provides result and Section VII concludes this article.

III. FACE DETECTION HAAR CLASSIFIER ALGORITHM

The face detection algorithm proposed by Viola and Jones is used as the basis of our design. The face detection algorithm looks for specific Haar features of a human face. When one of these features is found, the algorithm allows the face candidate to pass to the next stage of detection. A face candidate is a rectangular section of the original image called a sub-window. Generally these sub-windows have a fixed size (typically 24x24 pixels). This sub-window is often scaled in order to obtain a variety of different size faces. The algorithm scans the entire image with this window and denotes each respective section a face candidate [6]. The algorithm uses an integral image in order to process Haar features of a face candidate in constant time. It uses a cascade of stages which is used to eliminate non-face candidates quickly. Each stage consists of many different Haar features. Each feature is classified by a Haar feature classifier. The Haar feature classifiers generate an output which can then be provided to the stage comparator. The stage comparator sums the outputs of the Haar feature classifiers and compares this value with a stage threshold to determine if the stage should be passed. If all stages are passed the face candidate is concluded to be a face. These terms will be discussed in more detail in the following sections.

A. Integral Image

The integral image is defined as the summation of the pixel values of the original image. The value at any location \((x, y)\) of the integral image is the sum of the image’s pixels above and to the left of location \((x, y)\). Figure 1 illustrates the integral image generation. The simple rectangular features of an image are calculated using an intermediate representation of an image, called the integral image [1]. The integral image is an array containing the sums of the pixels’ intensity values located directly to the left of a pixel and directly above the pixel at location \((x, y)\) inclusive.

So if \(A(x, y)\) is the original image and \(AI[x, y]\) is the integral image then the integral image is computed as shown in equation 1 and illustrated in Figure 2.

\[
AI[x, y] = \sum_{x', y'} A(x', y')
\]

Figure 1. Summed Area of Integral Image

![Summed Area of Integral Image](image1.png)

Figure 2. Summed Area of Rotated Integral Image

![Summed Area of Rotated Integral Image](image2.png)
image and $AR[x, y]$ is the rotated integral image then the integral image is computed as shown in equation 2 an illustrated in Figure 2 and Figure 3.

$$AR[x, y] = \sum_{x', y'} A(x', y')$$ (2)

It only takes two passes to compute both integral image arrays, one for each array. Using the appropriate integral image and taking the difference between six to eight array elements forming two or three connected rectangles, a feature of any scale can be computed. Thus calculating a feature is extremely fast and efficient. It also means calculating features of various sizes requires the same effort as a feature of only two or three pixels. The detection of various sizes of the same object requires the same amount of effort and time as objects of similar sizes since scaling requires no additional effort.

B. Haar Features

Haar features are composed of either two or three rectangles. Face candidates are scanned and searched for Haar features of the current stage. The weight and size of each feature and the features themselves are generated using a machine learning algorithm from AdaBoost. The weights are constants generated by the learning algorithm. There are a variety of forms of features as seen below in Figure 4. Each Haar feature has a value that is calculated by taking the area of each rectangle, multiplying each by their respective weights, and then summing the results. The area of each rectangle is easily found using the integral image.

The coordinate of the any corner of a rectangle can be used to get the sum of all the pixels above and to the left of that location using the integral image. By using each corner of a rectangle, the area can be computed quickly as denoted by Figure 5. Since $L$ is subtracted off twice it must be added back on to get the correct area of the rectangle. The area of the rectangle $R$, denoted as the rectangle integral, can be computed as follows using the locations of the integral image:

$$L_4 - L_3 - L_2 + L_1$$

C. Haar Feature Classifier

A Haar feature classifier uses the rectangle integral to calculate the value of a feature. The Haar feature classifier multiplies the weight of each rectangle by its area and the results are added together. Several Haar feature classifiers compose a stage. A stage comparator sums all the Haar feature classifier results in a stage and compares this summation with a stage threshold. The threshold is also a constant obtained from the AdaBoost algorithm. Each stage does not have a set number of Haar features. Depending on the parameters of the training data individual stages can have a varying number of Haar features as shown in the Figure 6. For example, Viola and Jones’ data set used 2 features in the first stage and 10 in the second. All together they used a total of 38 stages and 6060 features. Our data set is based on the OpenCV data set which used 22 stages and 2135 features in total.

D. Cascade

The Viola and Jones face detection algorithm eliminates face candidates quickly using a cascade of stages. The cascade eliminates candidates by making stricter requirements in each stage with later stages being much more difficult for a candidate to pass. Candidates exit the cascade if they pass all stages or fail any stage. A face is detected if a candidate passes all stages. This process is shown in Figure 7.
IV. FACE DETECTION DESIGN AND ANALYSIS

This section will describe about the Face detection with itself which has several modules that are working together as one to make the system runs smoothly. The phase consists of capture image; Detect faces in the image, feature extraction, template comparison, declaration of matching template. The acquisition of face images can be done by acquiring the real time image from the OVA5647 CMOS Image Sensor interfaced with Raspberry pi High speed processor with GPU Processing. Furthermore the acquisition can also be done through real time remote monitoring either with IP or Wifi. The function of the face detection module is clarify whether the face is available during real time monitoring or detection of not. The face detection is done by scanning up an image for different scales and looking for some simple patterns as mentioned in the above section III. When the system detects the face, it will produce and sub-image that is scaled such that the face appears in the center and presented at a uniform size. OpenCV already provide algorithm to locate faces in still image and videos-Algorithm mentioned in section III. Haar classifier algorithm scans the image and creates a bounding box as returns for each detected face.

The feature extraction in face detection is done by localizing of the characteristics of face components (i.e., eyes, mouth, nose etc) in an image. In other terms the feature extraction is a step in face recognition where the system locates certain points on the faces such as corner and center of the eyes, tip of the nose, mouth etc. It analyzes spatial geometry of differential feature of a face. Result of this analyzing is a set of template generated for each face. The template consists of a reduced set of data which represent the real time face detected in bounded box. The template comparison is done with the template stored in the database. Two phases are there in this phase Identification and verification. These two term identification to detect the face in real time video and verification application for face recognition which scope out of this paper. The final phase of face detection is to declare the highest matching score resulted in the previous step.

The configuration will determine how the application should behave based on the desired security and operational consideration. The face detection methodology is shown in the Figure 8.

A. Face detection

System is capable of detecting the faces from the captured image for the purpose of prototype. From the above Section, face detection determines where in an image a face is located and it is done by scanning the different image scales and extracting the exact patterns to detect the face. The Prototype is to built with Haar-Like Feature function from OpenCV. Haar classifier detection is used to create a search window that slide through a image and check whether a certain region of an image looks like a face or not. Haar like features and a large set of very weak classifier uses a single feature to define a certain image as face or non face. Each feature is described by the template its coordinate relative to the search window origin and the size of the feature.

The search window quickly scanning the first classifier on the cascade as shown in the Figure 9, if the classifier returns false then the computation on that window also ends and results no detected face(false).Moreover, if the classifier returns true, then the window will be passed down to the next classifier in the cascade to do the exact same thing. When all classifier return true for that window, then the result will returns true also for that certain window face detected.
V. SYSTEM DESIGN

This paper is demonstrate and to utilize the portability of the Raspberry Pi by developing a security system using the camera module extension. The security system should have the capability of capturing a live video stream, detect any faces in the frame and recognize the face using a facial recognition algorithm. Feedback in the form of speech should be integrated into the security system shown in the below Figure 10 through remote monitoring for detecting the face interface with Raspberry Pi and OVA5647 CMOS Image Sensor which has High Definition Video processing.

The image processing tasks should be completed using the OpenCV library developed by Intel, which is compatible with the Raspberry Pi board. Figure 11 Shows the real time face detection system.

VI. RESULTS

The result of face detection is shown in Figure 12. Those are the frames extracted from the video. Sometimes, face detection algorithm may get more than one result even there is only one face in the frame, such as Figure 12. In this case, the post processing has been used. If the detector provides more than one rectangle, which indicates the position of the face, the distance of center points of these rectangles has been calculated. If this distance is smaller than a pre-set threshold, the average of these rectangles will be computed and set as the final position of the detected face.

In the paper we implement face tracking in the Python by using Viola Jones face detection. This method is verified and the limitations of the scheme are observed through testing and debugging our codes. And then, limited by Python performance, we shift to OpenCV to evaluate the speed of this face tracking scheme. We found the Viola Jones face detection is more suitable for real-time face detection since they requires less CPU resource and costs shorter time.

</tbody>
</table>

Table 1 shows the detection and non detection of faces. The face detection is done by means of Cascade Haar Classifier. Continuous tracking of the face is done with Cascade classifiers for detecting the real time face detection. The result are obtained from Figure 12, Figure 13 and Figure 14. From Image 1 the face is detected and the tracking is observed from face positions varying from [135 88], [262 71], [123 86]. Even multiple face detection is also possible with High Definition Video input.

CONCLUSION

Face detection and tracking is being challenging for many researchers with real time Image sensor. With the advancement the real time face detection in remote monitoring is help for building much efficient application. Moreover such technology can be useful in tracking the lost object under dynamic environment. Further enhancement of this work can be extended with stereo depth analysis of face detection using two image sensor interfaced with High speed Processor.
